# 10 Minutes to pandas

This is a short introduction to pandas, geared mainly for new users. You can see more complex recipes in the *Cookbook* 

Customarily, we import as follows:

```
In [1]: import pandas as pd
In [2]: import numpy as np
In [3]: import matplotlib.pyplot as plt
```

# **Object Creation**

See the Data Structure Intro section

Creating a **series** by passing a list of values, letting pandas create a default integer index:

```
In [4]: s = pd.Series([1,3,5,np.nan,6,8])
In [5]: s
Out[5]:
0     1
1     3
2     5
3     NaN
4     6
5     8
dtype: float64
```

Creating a **DataFrame** by passing a numpy array, with a datetime index and labeled columns:

```
2013-01-03 -0.861849 -2.104569 -0.494929 1.071804

2013-01-04 0.721555 -0.706771 -1.039575 0.271860

2013-01-05 -0.424972 0.567020 0.276232 -1.087401

2013-01-06 -0.673690 0.113648 -1.478427 0.524988
```

Creating a DataFrame by passing a dict of objects that can be converted to series-like.

```
In [10]: df2 = pd.DataFrame({ 'A' : 1.,
                               'B' : pd.Timestamp('20130102'),
                               'C' : pd.Series(1,index=list(range(4)),dtype='float
   . . . . :
                               'D' : np.array([3] * 4,dtype='int32'),
   . . . . :
                               'E' : pd.Categorical(["test","train","test","train"
   • • • • •
                               'F' : 'foo' })
   . . . . :
   . . . . :
In [11]: df2
Out[11]:
              B C D
                        E
                                F
  1 2013-01-02 1 3
                              foo
                        test
1
  1 2013-01-02 1 3 train
                              foo
2 1 2013-01-02 1 3 test foo
  1 2013-01-02 1 3 train foo
```

Having specific dtypes

If you're using IPython, tab completion for column names (as well as public attributes) is automatically enabled. Here's a subset of the attributes that will be completed:

```
In [13]: df2.<TAB>
df2.A
                       df2.boxplot
df2.abs
                       df2.C
df2.add
                       df2.clip
df2.add prefix
                       df2.clip lower
df2.add suffix
                       df2.clip upper
                       df2.columns
df2.align
df2.all
                       df2.combine
df2.any
                       df2.combineAdd
df2.append
                      df2.combine first
df2.apply
                      df2.combineMult
df2.applymap
                       df2.compound
df2.as blocks
                       df2.consolidate
df2.asfreq
                       df2.convert objects
df2.as matrix
                       df2.copy
```

```
df2.astype
                       df2.corr
df2.at
                       df2.corrwith
df2.at time
                       df2.count
df2.axes
                       df2.cov
df2.B
                       df2.cummax
df2.between time
                       df2.cummin
df2.bfill
                       df2.cumprod
df2.blocks
                       df2.cumsum
df2.bool
                       df2.D
```

As you can see, the columns A, B, C, and D are automatically tab completed. E is there as well; the rest of the attributes have been truncated for brevity.

# Viewing Data

See the Basics section

See the top & bottom rows of the frame

```
In [14]: df.head()
Out[14]:
                                      C

                                                                   0.524988
```

Sorting by an axis

Sorting by values

### Selection

**Note:** While standard Python / Numpy expressions for selecting and setting are intuitive and come in handy for interactive work, for production code, we recommend the optimized pandas data access methods, .at, .iat, .loc, .iloc and .ix.

See the indexing documentation Indexing and Selecting Data and MultiIndex / Advanced Indexing

### Getting

Selecting a single column, which yields a series, equivalent to df.A

```
In [23]: df['A']
Out[23]:
2013-01-01     0.469112
2013-01-02     1.212112
2013-01-03     -0.861849
2013-01-04     0.721555
2013-01-05     -0.424972
2013-01-06     -0.673690
Freq: D, Name: A, dtype: float64
```

Selecting via [], which slices the rows.

```
In [24]: df[0:3]
Out[24]:

A B C D

2013-01-01 0.469112 -0.282863 -1.509059 -1.135632
2013-01-02 1.212112 -0.173215 0.119209 -1.044236
2013-01-03 -0.861849 -2.104569 -0.494929 1.071804

In [25]: df['20130102':'20130104']
Out[25]:

A B C D

2013-01-02 1.212112 -0.173215 0.119209 -1.044236
2013-01-03 -0.861849 -2.104569 -0.494929 1.071804
2013-01-04 0.721555 -0.706771 -1.039575 0.271860
```

### Selection by Label

See more in Selection by Label

For getting a cross section using a label

```
In [26]: df.loc[dates[0]]
Out[26]:
A     0.469112
```

```
B -0.282863
C -1.509059
D -1.135632
Name: 2013-01-01 00:00:00, dtype: float64
```

Selecting on a multi-axis by label

Showing label slicing, both endpoints are included

Reduction in the dimensions of the returned object

```
In [29]: df.loc['20130102',['A','B']]
Out[29]:
A    1.212112
B    -0.173215
Name: 2013-01-02 00:00:00, dtype: float64
```

For getting a scalar value

```
In [30]: df.loc[dates[0],'A']
Out[30]: 0.46911229990718628
```

For getting fast access to a scalar (equiv to the prior method)

```
In [31]: df.at[dates[0],'A']
Out[31]: 0.46911229990718628
```

# Selection by Position

See more in Selection by Position

Select via the position of the passed integers

```
In [32]: df.iloc[3]
Out[32]:
A     0.721555
B     -0.706771
C     -1.039575
D     0.271860
Name: 2013-01-04 00:00:00, dtype: float64
```

By integer slices, acting similar to numpy/python

By lists of integer position locations, similar to the numpy/python style

For slicing rows explicitly

For slicing columns explicitly

For getting a value explicitly

```
In [37]: df.iloc[1,1]
Out[37]: -0.17321464905330858
```

For getting fast access to a scalar (equiv to the prior method)

```
In [38]: df.iat[1,1]
Out[38]: -0.17321464905330858
```

### **Boolean Indexing**

Using a single column's values to select data.

A where operation for getting.

```
In [40]: df[df > 0]
Out[40]:
                            В
                                      C
                                                D
2013-01-01 0.469112
                          NaN
                                    NaN
                                              NaN
2013-01-02 1.212112
                          NaN 0.119209
                                              NaN
2013-01-03
                                        1.071804
                NaN
                          NaN
                                    NaN
                                    NaN 0.271860
2013-01-04 0.721555
                          NaN
2013-01-05
                NaN 0.567020 0.276232
                                              NaN
2013-01-06
                NaN 0.113648
                                    NaN 0.524988
```

Using the isin() method for filtering:

```
In [41]: df2 = df.copy()
In [42]: df2['E'] = ['one', 'one', 'two', 'three', 'four', 'three']
In [43]: df2
Out[43]:
                                       С
                                                        Ε
                   Α
                             В
2013-01-01 0.469112 -0.282863 -1.509059 -1.135632
                                                      one
2013-01-02 1.212112 -0.173215 0.119209 -1.044236
                                                      one
2013-01-03 -0.861849 -2.104569 -0.494929
                                         1.071804
                                                      two
2013-01-04 0.721555 -0.706771 -1.039575 0.271860
                                                   three
2013-01-05 -0.424972 0.567020 0.276232 -1.087401
                                                     four
2013-01-06 -0.673690 0.113648 -1.478427 0.524988
                                                    three
```

### Setting

Setting a new column automatically aligns the data by the indexes

```
In [45]: s1 = pd.Series([1,2,3,4,5,6], index=pd.date_range('20130102', periods=6))
In [46]: s1
Out[46]:
2013-01-02     1
2013-01-03     2
2013-01-04     3
2013-01-05     4
2013-01-06     5
2013-01-07     6
Freq: D, dtype: int64
In [47]: df['F'] = s1
```

Setting values by label

```
In [48]: df.at[dates[0],'A'] = 0
```

Setting values by position

```
In [49]: df.iat[0,1] = 0
```

Setting by assigning with a numpy array

```
In [50]: df.loc[:,'D'] = np.array([5] * len(df))
```

The result of the prior setting operations

```
In [51]: df
Out[51]:
                            В

A where operation with setting.

# Missing Data

pandas primarily uses the value np.nan to represent missing data. It is by default not included in computations. See the *Missing Data section* 

Reindexing allows you to change/add/delete the index on a specified axis. This returns a copy of the data.

To drop any rows that have missing data.

Filling missing data

```
In [59]: df1.fillna(value=5)
```

```
Out[59]:
                                                 F
                                                    \mathbf{E}

In [70]: s.value_counts()
Out[70]:
4
     2
6
2
     2
dtype: int64
```

### String Methods

Series is equipped with a set of string processing methods in the *str* attribute that make it easy to operate on each element of the array, as in the code snippet below. Note that pattern-matching in *str* generally uses regular expressions by default (and in some cases always uses them). See more at *Vectorized String Methods*.

```
In [71]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'ca
In [72]: s.str.lower()
Out[72]:
1
        b
2
        С
3
     aaba
4
     baca
5
      NaN
6
     caba
7
      dog
      cat
dtype: object
```

# Merge

#### Concat

pandas provides various facilities for easily combining together Series, DataFrame, and Panel objects with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

See the *Merging section* 

Concatenating pandas objects together with concat():

```
In [73]: df = pd.DataFrame(np.random.randn(10, 4))
In [74]: df
Out[74]:
0 - 0.548702 \quad 1.467327 \quad -1.015962 \quad -0.483075
  1.637550 -1.217659 -0.291519 -1.745505

# Grouping

By "group by" we are referring to a process involving one or more of the following steps

Splitting the data into groups based on some criteria

- Applying a function to each group independently
- Combining the results into a data structure

#### See the *Grouping section*

```
In [86]: df = pd.DataFrame({'A' : ['foo', 'bar', 'foo', 'bar',
                                   'foo', 'bar', 'foo',
                                                        'foo'],
                            'B' : ['one', 'one', 'two', 'three',
                                   'two', 'two', 'one', 'three'],
                            'C': np.random.randn(8),
                            'D' : np.random.randn(8)})
   . . . . :
In [87]: df
Out[87]:
                      C
     Α
            В
          one -1.202872 -0.055224
0

              1.928123 -1.623033
```

Grouping and then applying a function sum to the resulting groups.

Grouping by multiple columns forms a hierarchical index, which we then apply the function.

# Reshaping

See the sections on Hierarchical Indexing and Reshaping.

#### Stack

```
In [90]: tuples = list(zip(*[['bar', 'bar', 'baz', 'baz',
                               'foo', 'foo', 'qux', 'qux'],
                              ['one', 'two', 'one', 'two',
   . . . . :
                               'one', 'two', 'one', 'two']]))
   . . . . :
   . . . . :
In [91]: index = pd.MultiIndex.from tuples(tuples, names=['first', 'second'])
In [92]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=['A', 'B']
In [93]: df2 = df[:4]
In [94]: df2
Out[94]:
                      Α
                                В
first second
              0.029399 -0.542108
bar
      one
      two
              0.282696 - 0.087302
             -1.575170 1.771208
baz
      one
      two
              0.816482 1.100230
```

The stack() method "compresses" a level in the DataFrame's columns.

```
In [95]: stacked = df2.stack()
In [96]: stacked
Out[96]:
first second
bar
       one
               Α
                   0.029399
               В
                   -0.542108
               Α
                    0.282696
       two
               В
                   -0.087302
baz
                   -1.575170
       one
               Α
               В
                   1.771208
               Α
                    0.816482
       t.wo
                    1.100230
dtype: float64
```

With a "stacked" DataFrame or Series (having a MultiIndex as the index), the inverse operation of stack() is unstack(), which by default unstacks the last level:

```
Out[98]:
second
              one
                         two
first
bar
      A 0.029399
                   0.282696
      B -0.542108 -0.087302
baz
      A -1.575170
                   0.816482
        1.771208
                   1.100230
In [99]: stacked.unstack(0)
Out[99]:
first
               bar
                          baz
second
one
       A 0.029399 -1.575170
       B -0.542108
                    1.771208
two
       A 0.282696
                    0.816482
       B -0.087302
                    1.100230
```

#### **Pivot Tables**

See the section on Pivot Tables.

```
In [100]: df = pd.DataFrame({'A' : ['one', 'one', 'two', 'three'] * 3,
                             'B' : ['A', 'B', 'C'] * 4,
                             'C': ['foo', 'foo', 'foo', 'bar', 'bar', 'bar'] * 2
   . . . . . :
                             'D' : np.random.randn(12),
                             'E' : np.random.randn(12)})
In [101]: df
Out[101]:
        Α
          В
                C
                          D
0
              foo 1.418757 -0.179666
      one
          Α
1
      one
           В
              foo -1.879024
                             1.291836
2
      two C
              foo
                   0.536826 - 0.009614
3
    three A
              bar
                   1.006160 0.392149
4
              bar -0.029716 0.264599
      one B
5
          C
              bar -1.146178 -0.057409
      one
6
      two A foo 0.100900 -1.425638
7
             foo -1.035018 1.024098
    three B
8
      one
          C
              foo
                   0.314665 - 0.106062
9
      one A
              bar -0.773723 1.824375
10
      two
          В
              bar -1.170653 0.595974
11
    three
          С
              bar
                   0.648740
                            1.167115
```

We can produce pivot tables from this data very easily:

```
B NaN -1.035018
C 0.648740 NaN
two A NaN 0.100900
B -1.170653 NaN
C NaN 0.536826
```

## **Time Series**

pandas has simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minutely data). This is extremely common in, but not limited to, financial applications. See the *Time Series section* 

Time zone representation

```
In [106]: rng = pd.date range('3/6/2012 00:00', periods=5, freq='D')
In [107]: ts = pd.Series(np.random.randn(len(rng)), rng)
In [108]: ts
Out[108]:
2012-03-06
            0.464000
2012-03-07 0.227371
2012-03-08
            -0.496922
2012-03-09
             0.306389
2012-03-10
            -2.290613
Freq: D, dtype: float64
In [109]: ts_utc = ts.tz_localize('UTC')
In [110]: ts_utc
Out[110]:
2012-03-06 00:00:00+00:00
                           0.464000
2012-03-07 00:00:00+00:00
                            0.227371
2012-03-08 00:00:00+00:00
                           -0.496922
2012-03-09 00:00:00+00:00
                            0.306389
2012-03-10 00:00:00+00:00
                          -2.290613
Freq: D, dtype: float64
```

Convert to another time zone

```
In [111]: ts_utc.tz_convert('US/Eastern')
Out[111]:
```

Converting between time span representations

```
In [112]: rng = pd.date range('1/1/2012', periods=5, freq='M')
In [113]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
In [114]: ts
Out[114]:
2012-01-31 -1.134623
2012-02-29 -1.561819
2012-03-31 -0.260838
2012-04-30 0.281957
            1.523962
2012-05-31
Freq: M, dtype: float64
In [115]: ps = ts.to period()
In [116]: ps
Out[116]:
2012-01 -1.134623
2012-02 -1.561819
2012-03 -0.260838
2012-04 0.281957
2012-05
         1.523962
Freq: M, dtype: float64
In [117]: ps.to_timestamp()
Out[117]:
2012-01-01 -1.134623
2012-02-01 -1.561819
2012-03-01 -0.260838
2012-04-01
            0.281957
2012-05-01
          1.523962
Freq: MS, dtype: float64
```

Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

```
In [118]: prng = pd.period_range('1990Q1', '2000Q4', freq='Q-NOV')
In [119]: ts = pd.Series(np.random.randn(len(prng)), prng)
In [120]: ts.index = (prng.asfreq('M', 'e') + 1).asfreq('H', 's') + 9
In [121]: ts.head()
Out[121]:
1990-03-01 09:00  -0.902937
```

# Categoricals

Since version 0.15, pandas can include categorical data in a DataFrame. For full docs, see the categorical introduction and the API documentation.

```
In [122]: df = pd.DataFrame({"id":[1,2,3,4,5,6], "raw_grade":['a', 'b', 'b', 'a',
```

Convert the raw grades to a categorical data type.

Rename the categories to more meaningful names (assigning to series.cat.categories is inplace!)

```
In [125]: df["grade"].cat.categories = ["very good", "good", "very bad"]
```

Reorder the categories and simultaneously add the missing categories (methods under series .cat return a new series per default).

```
In [126]: df["grade"] = df["grade"].cat.set_categories(["very bad", "bad", "mediu
In [127]: df["grade"]
Out[127]:
0    very good
1        good
2        good
3    very good
4    very good
5    very bad
Name: grade, dtype: category
Categories (5, object): [very bad, bad, medium, good, very good]
```

Sorting is per order in the categories, not lexical order.

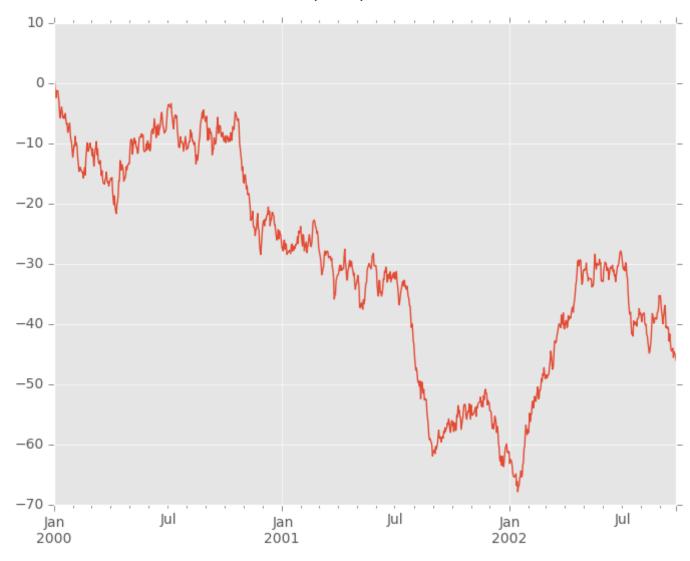

```
In [128]: df.sort_values(by="grade")
Out[128]:
   id raw_grade
                     grade
                  very bad
              е
1
    2
              b
                      good
2
    3
              b
                      good
0
    1
              a
                very good
3
    4
              a very good
4
              a very good
```

Grouping by a categorical column shows also empty categories.

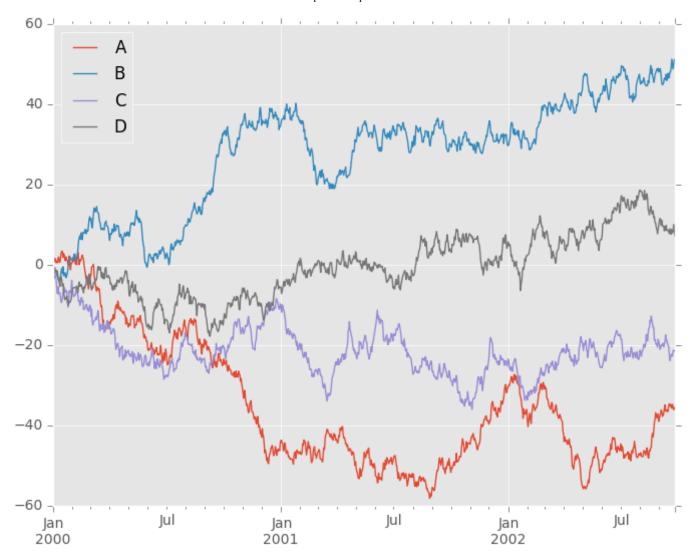

# **Plotting**

Plotting docs.

```
In [130]: ts = pd.Series(np.random.randn(1000), index=pd.date_range('1/1/2000', p
In [131]: ts = ts.cumsum()
In [132]: ts.plot()
Out[132]: <matplotlib.axes._subplots.AxesSubplot at 0xae3696ac>
```

On DataFrame, plot() is a convenience to plot all of the columns with labels:

# Getting Data In/Out

**CSV** 

#### Writing to a csv file

```
In [136]: df.to_csv('foo.csv')
```

#### Reading from a csv file

```
In [137]: pd.read_csv('foo.csv')
Out[137]:

#### Excel

Reading and writing to MS Excel

Writing to an excel file

```
In [140]: df.to_excel('foo.xlsx', sheet_name='Sheet1')
```

Reading from an excel file

```
In [141]: pd.read excel('foo.xlsx', 'Sheet1', index col=None, na values=['NA'])
Out[141]:
                                         C

### Gotchas

If you are trying an operation and you see an exception like:

```
>>> if pd.Series([False, True, False]):
    print("I was true")
Traceback
...
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.a
```

See *Comparisons* for an explanation and what to do.

See Gotchas as well.
